ABSTRACT

**A PARTITION AND METHOD FOR CONTROLLING
THE TEMPERATURE IN AN AREA**

Partition for separating the interior of a building construction such as a greenhouse from the surroundings. This partition is fitted at an inclination and is of multi-walled, such as double-walled, construction. According to the invention, the separation wall facing the interior of the building construction is provided with a layer of water with such a small thickness that a free space remains between the wall of the partition facing the outside and the layer of water. It has been found that the temperature in the interior of the building construction can be accurately controlled in this way. By means of the choice of the liquid used to build up the layer, it is possible either not to influence the transmission of light or to modify the transmission of light.
